===== Our study showed that the Mac Pro's increase in processing performance was more than the quadrupled performance of an Intel Core 2 Duo. An increase of approximately 10,000 times was observed in the GCD performance of the Mac Pro versus the computer without a GPU. This increase is a lot more than needed to be able to write to local HDDs and SDDs. For the random access needs of the data in the L2 Cache, we observed an increase in performance of approximately 10,000 times. Comparing all three serialization methods, the GPU implementation leads to an increase in performance that is approximately 1,000 times the CPU implementation, and a factor of 100,000 times the non-GPU implementation. However, if we add further components into this server, such as adding a separate Ethernet or SATA card to the Mac Pro, the gain in performance is not as large. The following Table [3]{#Tab3}{ref-type="table"} shows the performance of a dual-CPU Mac Pro with a single Ethernet card. The results show that the performance of the non-GPU implementation is about 2,000 times that of the single-CPU computer and is a bit more than 10,000 times that of the GPU implementation. Also, the performance of the CPU implementation is approximately the same as the performance of the single-CPU computer. This is because in the GPU implementation, many of the operations are done on the GPU, so there is less idle time on the CPU for the higher-level algorithms.
